| 0.1      | Objectives . . . . .                          | 1        |
| <b>1</b> | <b>Branching</b>                              | <b>1</b> |
| 1.1      | Instruction Pointer . . . . .                 | 2        |
| 1.2      | JMP Instruction . . . . .                     | 2        |
| 1.2.1    | Relative vs Absolute Offset Address . . . . . | 2        |
| 1.2.2    | Types of Jumps: . . . . .                     | 3        |

## 0.1 Objectives

## 1 Branching

- By default, the CPU loads and executes programs sequentially.
- A branch, or transfer of control, is a way of altering the order in which statements are executed.
- There are two basic types of transfer:

1. **Unconditional transfer**, in which a transfer is occurred unconditionally.
2. **Conditional transfer**, in which a transfer is occurred based on a certain condition.

## 1.1 Instruction Pointer

- The EIP, or instruction pointer , register contains the address of the next instruction to be executed. Certain machine instructions manipulate EIP, causing the program to branch to a new location.

## 1.2 JMP Instruction

### Syntax

```
JMP <destination>
```

- The JMP instruction causes an unconditional transfer to a destination address.
- The destination (target) operand specifies the address of the instruction being jumped to. This operand can be an immediate value, a general-purpose register, or a memory location.

In this course, we only consider the immediate value for the destination operand.

### 1.2.1 Relative vs Absolute Offset Address

- The destination address, within the instruction stream, can be relative offset or absolute offset

- A relative offset is a signed displacement to the current value of the EIP.

$$\text{Offset Address} = \text{EIP} + \text{DEST}$$

- An absolute address is an offset from the base of the code segment.

$$\text{Offset Address} = \text{DEST}$$

### 1.2.2 Types of Jumps:

1. Near Jump:
2. **Short jump:**
3. Far Jump
